**Savannah Resources Plc  
(AIM: SAV) ('Savannah', or the 'Company')**

**Barroso Lithium Project - JORC Resource Update**

***JORC Resources increased by 40% at the Barroso Lithium Project to 39Mt including 27Mt in the Measured and Indicated categories***

Savannah Resources Plc, the developer of the Barroso Lithium Project (the 'Project') in Portugal, a 'Strategic Project' under the European Critical Raw Materials Act, is pleased to announce a 40% increase in the Project's overall JORC (2012) compliant Resource to over 39Mt and a corresponding 41% increase in the Project's higher quality Measured and Indicated ('M&I') Resources to nearly 27Mt. With average grade maintained at 1.05%  $\text{Li}_2\text{O}$ , the new estimate takes the Project's lithium resources past 1Mt of lithium carbonate equivalent for the first time. Furthermore, at nearly 27Mt, the new M&I Resources from which the Project's first JORC ore reserve will be created, approximately equate to the entire previous resource.

Accompanying the increased and upgraded resource is a new Exploration Target<sup>1</sup>, which for the first time, includes targets for each of the Project's five orebodies as well as the remainder of the Project's lease areas. At 35-62Mt at 0.9%-1.2%  $\text{Li}_2\text{O}^2$  this represents more than a 200% increase on the previous Exploration Target.

This substantial growth in resources, all drawn from within the Project's lease areas, significantly increases its strategic importance to all its stakeholders. This is both as a major contributor of lithium raw material to Europe's battery value chain, but also as a significant, long term, value creator for the local region, the Portuguese economy and Savannah's shareholders.

**Highlights:**

- JORC (2012) compliant Resources at the Project increased by 40% to 39.1Mt at 1.05%  $\text{Li}_2\text{O}$  based on extensions to existing orebodies all located within the Project's existing lease areas.
- A larger resource offers the potential for the Project's producing life to be longer and economic and social benefits to be greater, while constraining development to the lease areas.
- A new Exploration Target<sup>3</sup>, estimated from drilling and surface exploration data, outlines the potential for an additional 35 to 62Mt at a range from 0.9% to 1.2%  $\text{Li}_2\text{O}^4$ . This represents more than a 200% increase from the previous Exploration Target estimate.
- Contained  $\text{Li}_2\text{O}$  resources increased by 41% to 411,900 tonnes due to a slight increase in average grade. The new JORC Resource takes contained  $\text{Li}_2\text{O}$  mineralisation over the 1Mt lithium carbonate equivalent level for the first time (1.019Mt).
- Measured and Indicated resources increased by 42% to 26.6Mt at 1.05%  $\text{Li}_2\text{O}$ , representing 68% of the total new resource and equating to 95% of the total May 2024 JORC Resource.
- Virtually all the 2023 Scoping Study mining inventory (20.5Mt) was converted into Measured and Indicated Resources, thus reinforcing the quality of the economic study work done to date.
- All deposits remain open both along strike and down dip, offering further upside potential.
- The new resource estimate will form the basis for the Project's maiden JORC Reserve estimate, which will underpin the Definitive Feasibility Study ('DFS'), paving the way for the Project to advance to production as Europe's largest spodumene lithium deposit.

**Savannah's Chief Technical Officer, Dale Ferguson said** "The primary goal of the recent resource-focused drilling, which we completed in July, was to upgrade the existing resources at Pinheiro, Reservatório and Grandão in preparation for the Project's maiden reserve estimate for the DFS. However, the drilling also confirmed several orebody extensions and consistently returned impressive assays. Hence, it became clear that we would be able to report a substantial increase in tonnage as well. It's great to be able to do that today with a 40% overall increase in tonnage, including a 188% and 140% increase at Reservatório and Pinheiro respectively, and a 42% increase in Measured and Indicated resources.

"Importantly the updated resource also confirms the grade consistency of the mineralisation, with the Project retaining its overall 1.05% Li<sub>2</sub>O average grade. The updated resource also continues to confirm past exploration targets. Hence this gives us confidence in our ability to convert the substantially increased Exploration Target, which we have also announced today, into more resources over time."

**Savannah's Chief Executive Officer, Emanuel Proença, added** "My thanks go to the exploration & geology teams for their tireless work to complete the drilling and produce this significant increase in the Project's resources and exploration targets. It's very exciting to witness this next step in the Project's evolution and to get further insight into the potential the Project's leases have to offer in terms of additional lithium prospectivity.

"The expansion of the resource close to 40Mt gives good visibility through to a longer producing life than was envisaged in the 2023 Scoping Study. This has clear benefits for all stakeholders as the potential now exists for the Project to make a greater contribution in terms of lithium production, value and job creation, tax and royalty payments, and numerous other socio-economic benefits over a longer period. Furthermore, when the resources are considered alongside the much increased Exploration Target we have also announced, it is possible to envisage that the Project could pass the milestone of 100Mt of resources at some point in the future - benefiting our growing team, our partners, our region, Portugal and Europe, and leaving countless barrels of oil in the ground."

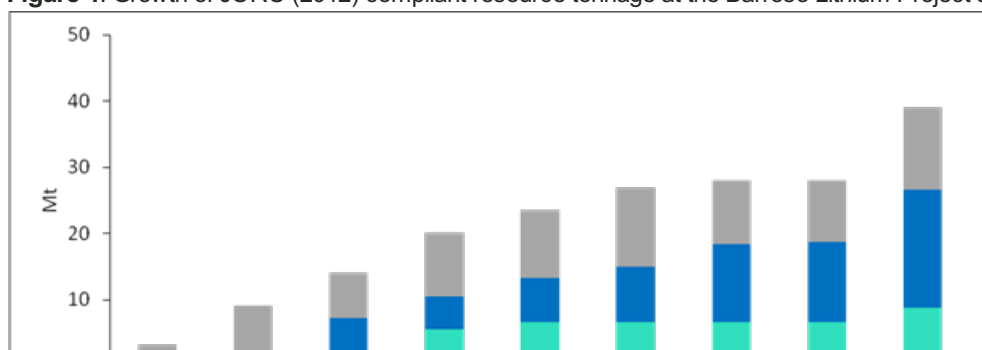

<sup>1,2,3,4</sup>*Cautionary Statement: The potential quantity and grade of the Exploration Targets is conceptual in nature, there has been insufficient exploration work to estimate a mineral resource and it is uncertain if further exploration will result in defining a mineral resource.*

<sup>5</sup>Cautionary Statement: The potential quantity and grade of the Exploration Targets is conceptual in nature, there has been insufficient exploration work to estimate a mineral resource and it is uncertain if further exploration will result in defining a mineral resource.

**Figure 2.** Growth in Upper limit of Exploration Target<sup>6</sup> tonnage at the Barroso Lithium Project since 2017

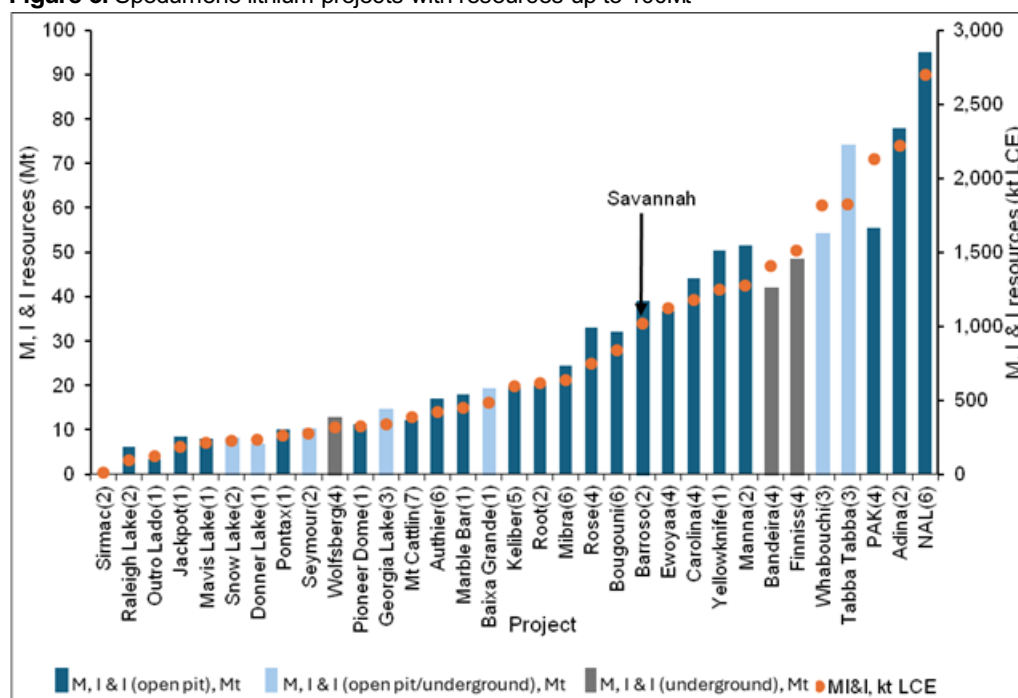

### Industry comparison

Following this significant upgrade to its JORC Resource base, the Barroso Lithium Project retains its position as the largest spodumene lithium resource in Europe. Furthermore, it now compares even more favorably to a wide group of spodumene peer projects from around the world, which are at various stages along the development curve, including some in construction and production.

With all its orebodies remaining open, and numerous prospects on the leases still to be drilled to JORC Resource standards, significant opportunities remain to further increase the Project's resource over time. This would then present a great opportunity to extend the life of the operation, amplify the socio-economic benefits the Project can bring to the region, and increase the positive impact it can have in building Portugal's new lithium industry well into the future.

<sup>6</sup>Cautionary Statement: The potential quantity and grade of the Exploration Targets is conceptual in nature, there has been insufficient exploration work to estimate a mineral resource and it is uncertain if further exploration will result in defining a mineral resource.

### Further Information

Mineral Resource Estimates for the Grandão, Reservatório, Pinheiro and NOA lithium deposits have been prepared by Ashmore Advisory Pty Ltd, an external and independent mining consultancy. The deposits form part of Savannah's Barroso Lithium Project, located in northern Portugal and are highlighted in **Figure 4**. The Mineral Resource Estimates for the deposits at the Project have been classified as Measured, Indicated and Inferred Mineral Resource in accordance with the JORC Code, 2012 Edition and are summarised in **Tables 3 and 4 and Appendix 1**. In addition, an updated exploration target<sup>7</sup> for the existing resources and other identified pegmatites within the C-100 licence, adjacent C-100 licence extension application<sup>8</sup> area and Aldeia licence<sup>9</sup> (**Figure 5**) was also estimated in accordance with the JORC Code, 2012 Edition and are summarised in **Tables 5-9**.

<sup>7</sup> Cautionary Statement: The potential quantity and grade of the Exploration Targets is conceptual in nature, there has been insufficient exploration work to estimate a mineral resource and it is uncertain if further exploration will result in defining a mineral resource.

<sup>8</sup> Part of the Reservatório deposit is situated within a 250m extension zone of the C-100 licence, which is under application. Savannah has received written confirmation from the DGEG that under article 24 of Decree-Law no. 88/90 of March 16 being relevant justification based on the resources allocated exploited and intended, Savannah has been approved an expansion up to 250m of the C-100 mining concession in specific areas where a resource has been defined and the requirement for the expansion can be justified.

<sup>9</sup> Savannah has the right to purchase the adjacent Aldeia Mining Lease ("Aldeia") and continues to evaluate this potential acquisition. Further details of the proposed transaction can be found in note 19 to the accounts in the 2024 Annual Report.

## Orebody Descriptions

### Grandão

At the Grandão deposit, the largest orebody at the Project, the upper part of the deposit occurs within a broad, flat-lying pegmatite body with a typical thickness of 20 to 40m. A lower zone of the deposit comprises numerous steep dipping dykes which are 10 to 20m in true width (**Figures 6-7**). Small parallel lenses of spodumene pegmatite have also been interpreted. All orebodies remain open both along strike and down dip.

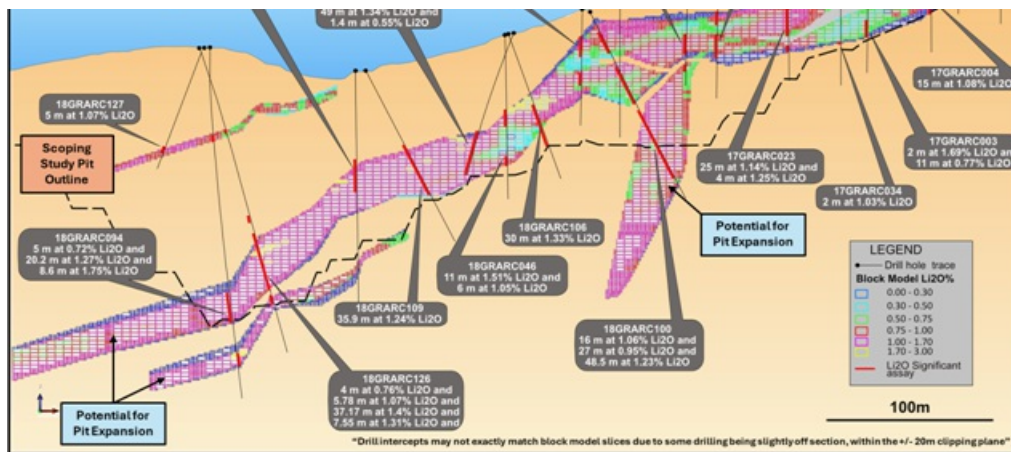

<sup>10,11,12</sup>Cautionary Statement: The potential quantity and grade of the Exploration Targets is conceptual in nature, there has been insufficient exploration work to estimate a mineral resource and it is uncertain if further exploration will result in defining a mineral resource.

**Figure 6.** Grandão Resource Model (Main Domains) Coloured by Li<sub>2</sub>O Content (looking Northeast)

**Figure 7.** Grandão Cross Section (looking North)

## Reservatório

At the Reservatório deposit, mineralisation is largely hosted within a single, tabular pegmatite with several minor parallel lenses. It strikes broadly NE-SW and dips to the NW at 15° to 30° and varies in thickness from 20m to 50m. The deposit outcrops over a strike length of approximately 550m and remains open, particularly at depth (**Figures 8-9**).

**Figure 8.** Reservatório Resource Model (Main Domains) Coloured by Li<sub>2</sub>O Content (looking Southeast)

**Figure 9.** Reservatório Cross Section (looking Northeast)

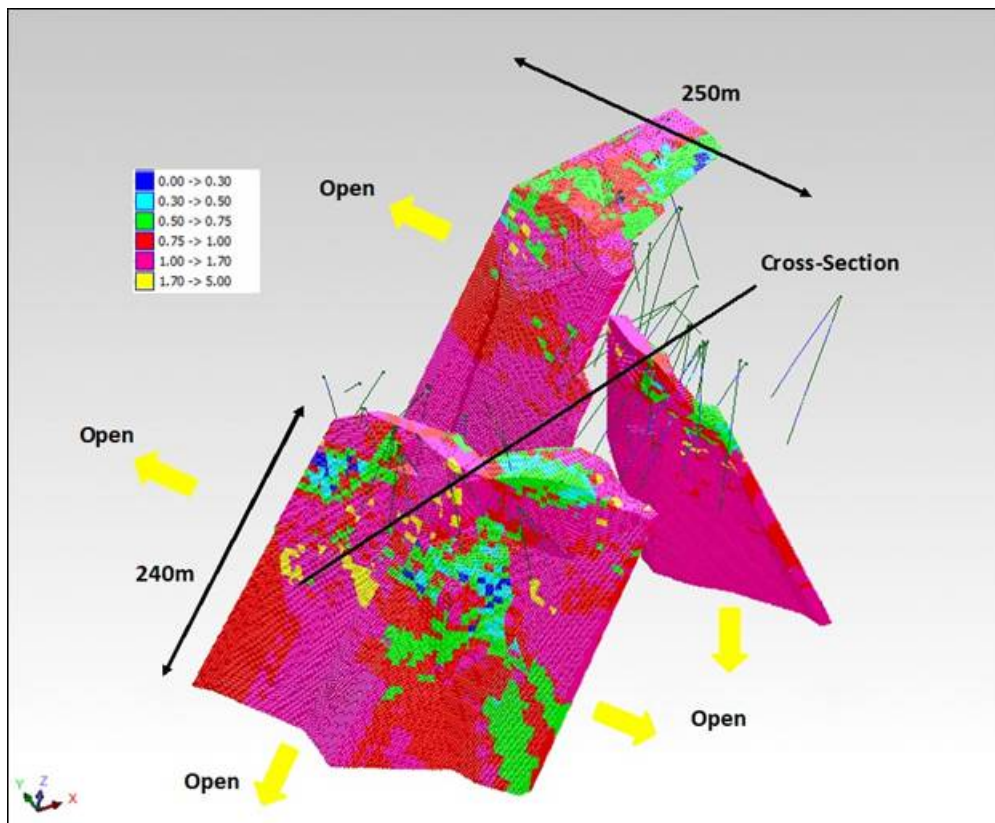

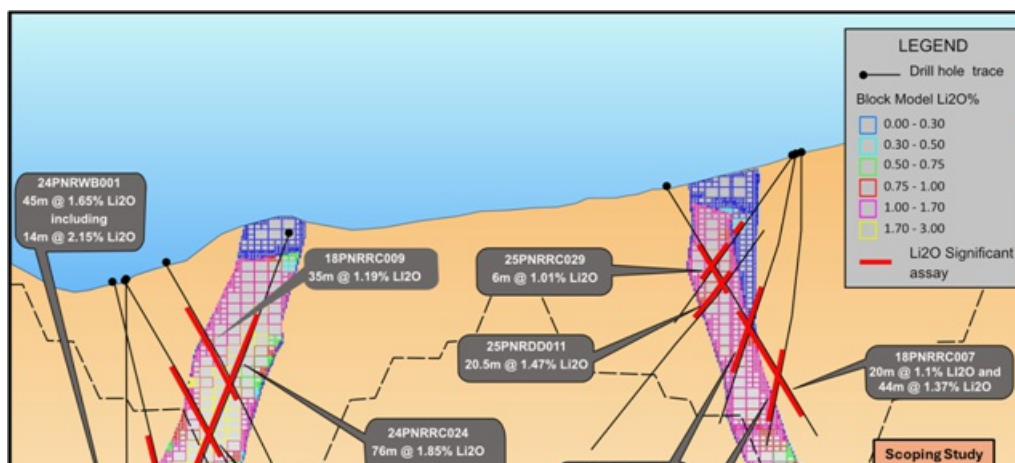

### Pinheiro

At the Pinheiro deposit, mineralisation is hosted in three steep dipping, north trending tabular pegmatite pods 20 to 30m in true width. The deposit outcrops over a strike length of approximately 240m and remains open along strike and at depth (**Figures 10-11**).

**Figure 10.** Pinheiro Resource Model (Main Domain) Coloured by Li<sub>2</sub>O Content (looking Southeast)

**Figure 11.** Pinheiro Cross Section (looking Northeast)

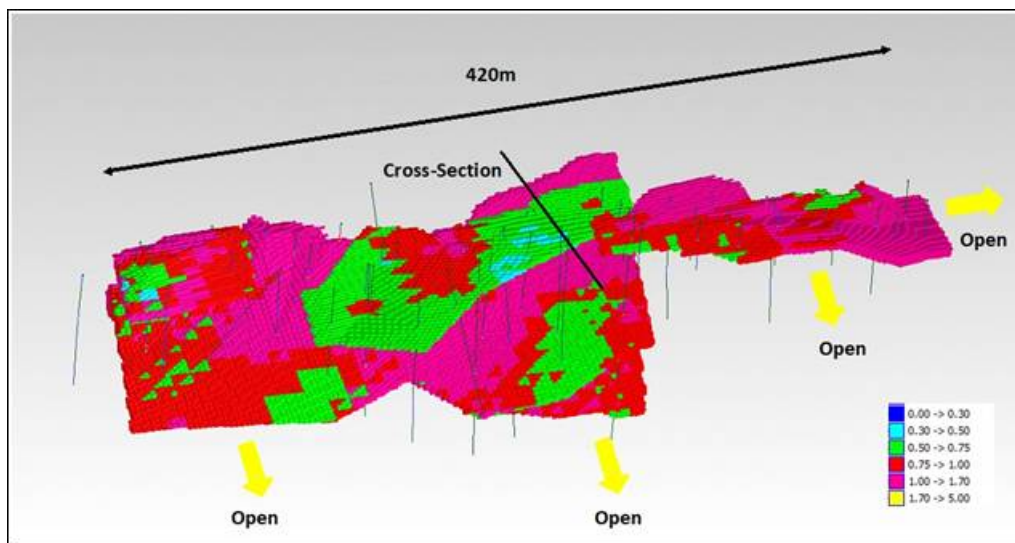

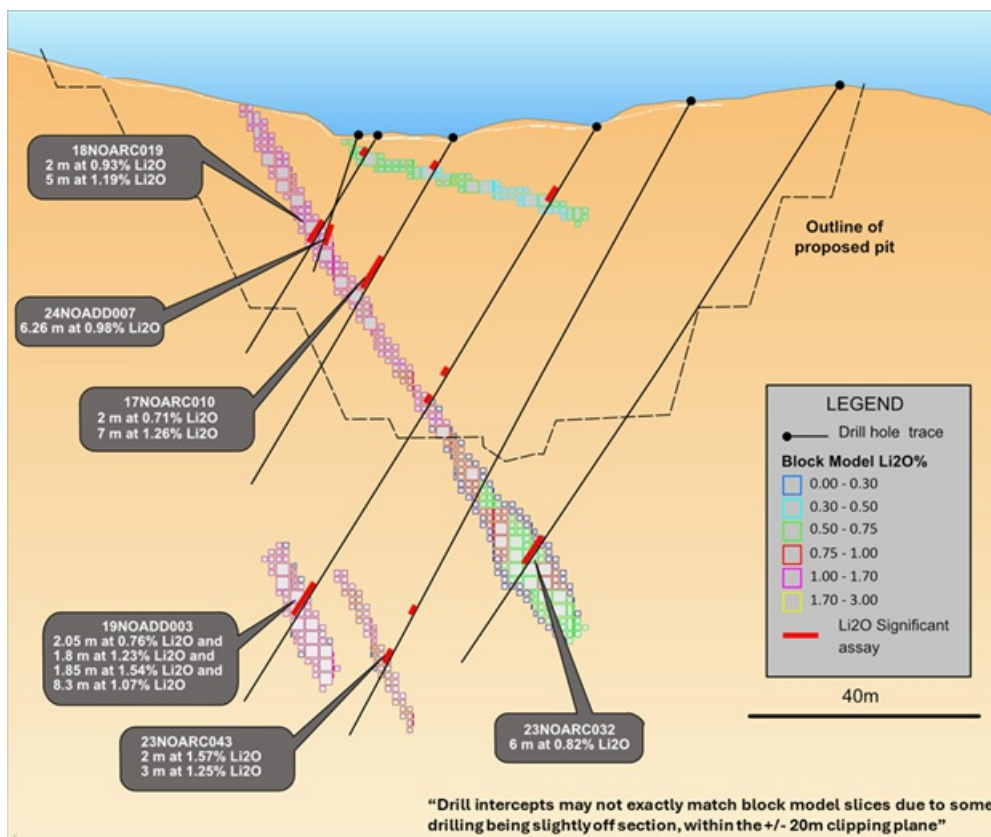

## NOA

At the NOA deposit, the host pegmatite is a steep dipping, northwest trending body which is 5-10m in true width. It has been mapped in outcrop over much of the interpreted 440m strike length of the Mineral Resource (**Figures 12-13**).

**Figure 12.** NOA Resource Model (Main Domains) Coloured by Li<sub>2</sub>O Content (looking Southwest)

**Figure 13.** NOA Cross Section (looking West)

## **Geology**

At the Barroso Lithium Project, lithium mineralisation occurs predominantly in the form of spodumene-bearing pegmatites which are hosted in metapelitic and mica schists and occasionally carbonate schists of upper Ordovician to lower Devonian age. Lithium is present in most pegmatite compositions and laboratory test work confirms that the lithium is almost exclusively within spodumene. Distinct lithium grade zonation occurs within the pegmatites, with weakly mineralised zones often evident at the margins of the intrusions. Minor xenoliths and inliers of schist are observed on occasions.

The weathering profiles comprises a shallow, surficial zone of weak to moderate oxidation, particularly of the schistose country rock. For each deposit, Ashmore generated a top of fresh rock surface to differentiate weathered and fresh material.

Mineral Resources have now been defined in five separate pegmatite zones - Grandão, Reservatório, Pinheiro, NOA and Aldeia.

The Grandão deposit comprises what is interpreted to be one main pegmatite intrusion and a series of minor mineralised intrusions. The upper part of the deposit occurs within a broad, flat-lying pegmatite body with a typical thickness of 20 to 40m. A lower zone of the deposit comprises numerous steep dipping dykes which are 10 to 20m in true width. Small parallel lenses of spodumene pegmatite have also been interpreted.

At the Reservatório deposit, mineralisation is largely hosted within a single, tabular pegmatite with several minor parallel lenses. It strikes broadly NE-SW and dips to the NW at 15° to 30° and varies in thickness from 20m to 50m. The deposit outcrops over a strike length of approximately 550m and remains open, particularly at depth.

At the Pinheiro deposit, mineralisation is hosted in three steep dipping, north trending tabular pegmatite pods 20 to 30m in true width. The deposit outcrops over a strike length of approximately 240m and remains open along strike and at depth.

At the NOA deposit, the host pegmatite is a steep dipping, northwest trending body which is 5-10m in true width. It has been mapped in outcrop over much of the interpreted 440m strike length of the Mineral Resource. The weathering profile comprises a shallow, surficial zone of weak to moderate oxidation, particularly of the schistose country rock.

## **Drilling**

The Grandão deposit is defined by a total of 110 reverse circulation ("RC") holes, 32 reverse circulation holes with diamond tails ("RCD"), 32 diamond ("DD") holes and a percussion hole. The holes were drilled on approximate spacings of 20m to 40m on 40m to 50m spaced cross sections.

The Reservatório deposit is defined by a total of 72 RC holes, 19 RCD and 16 DD holes. The holes were drilled on approximate spacings of 20m to 40m on 40m spaced cross sections.

The Pinheiro deposit is defined by a total of 3 percussion holes, 26 RC holes, 5 RCD and 17 DD holes. Drill hole spacing is as close as 20m by 10m; but is predominantly 20m by 20m to 40m by 40m across the deposit.

The NOA deposit is defined by a total of 58 RC holes and 7 DD holes. The holes were drilled on an approximate hole spacing of 25m by 20m, out to 40m by 40m.

All holes were completed by Savannah since 2017.

Drill collar locations are recorded in Universal Traverse Mercator ("UTM") coordinates using differential GPS. All Savannah drilling has been down-hole surveyed using a gyroscopic tool.

## **Sampling and Sub-Sampling Techniques**

RC drilling by Savannah was carried out using a face sampling hammer (120mm). Savannah reported that drilling conditions were good, samples were generally dry and measured sample recoveries were good other than some recorded sample loss near the hole collar in some holes.

Samples were collected at 1m intervals from pegmatite zones. For the 2017 drilling, composite sampling of typically 4m was conducted in the surrounding schists. For drilling conducted since 2018, schist was only sampled for 5m each side of the pegmatites. The 1m samples were collected through a rig-mounted riffle splitter and were 4-6kg in weight.

Diamond drilling commenced in PQ diameter and reduced to HQ diameter when competent rock was intersected. Core recovery was excellent. For sampling, core was aligned then marked with a centre line. Core was cut with a saw with half-core taken for bulk metallurgical samples. The remaining half core was cut again to produce quarter core samples for analysis. Samples were to geological boundaries then typically at 1m intervals.

### **Sample Analysis Method**

The samples were analysed using ALS Laboratories ME-MS89L Super Trace method which combines a sodium peroxide fusion with ICP-MS instrumentation utilising collision/reaction cell technologies to provide the lowest detection limits available.

A prepared sample (0.2g) is added to sodium peroxide flux, mixed well and then fused in at 670°C. The resulting melt is cooled and then dissolved in 30% hydrochloric acid. This solution is then analysed by ICP-MS and the results are corrected for spectral inter-element interferences. The final solution is then analysed by ICP-MS, with results corrected for spectral inter-element interferences.

QA/QC protocols were in place for the drilling programmes and included the use of blanks, standards and field duplicates. The data has confirmed the quality of the sampling and assaying for use in Mineral Resource estimation.

### **Estimation Methodology**

For the Mineral Resource Estimates, Surpac block models were generated using block sizes approximately a quarter to a half the predominant drill hole spacing, with sub-blocking. The block sizes selected for each deposit were guided by Kriging Neighbourhood Analysis ("KNA").

Interpretation of the pegmatite dykes was completed using detailed geological logging and Fe geochemistry. Wireframes of the pegmatites were prepared and within those the sample data was extracted and analysed. A clear break in the grade distribution occurs at 0.5% Li<sub>2</sub>O and this grade threshold was used to prepare the internal grade domains for estimation.

Sample data was composited into 1m intervals. The pegmatites at the deposit were estimated using ordinary kriging ("OK") grade interpolation. Up to three passes were used in the grade interpolation with first pass ranges ranging between 40 and 60m. A minimum of 6 to 8 samples and a maximum of 12 to 16 samples were used to estimate each block model. No extreme high grades were present in the Li<sub>2</sub>O and Fe data, and the CV of less than 1 for all elements suggested that high grade cuts were not required. However, a small number of outliers of tantalum ('Ta') were present across the deposits and high-grade cuts of 60 to 100ppm were applied to Ta values.

Iron contamination via abrasion of RC drilling equipment and/or sample preparation equipment is a recognized problem when evaluating lithium deposits. To test the potential for iron contamination at the Project, Savannah carried out a preliminary programme of check assays and a series of comparisons were undertaken on samples from the Grandão deposit.

It was concluded from the Grandão study that a significant proportion of the iron being reported in the drilling assay data was introduced as contamination during the sample preparation process. It was determined that the amount of contamination was proportional to the lithium content of the samples. A regression formula was calculated using all samples, with the derived regression formula being:

$$\text{Fe}_{\text{contamination}} = (0.1734 * \text{Li}_2\text{O grade}) + 0.2308.$$

The amount of Fe contamination was determined using the derived regression formula. A new field

The amount of Fe contamination was determined using the derived regression formula. A new field "Fe\_factored" was inserted into the drill hole database, and the original Fe value minus the calculated contamination was stored in that field. This allowed a "Fe\_factored" value to be extracted from the database and used for grade estimation in the Mineral Resource.

Bulk density values applied to the estimates were based on a substantial number of drill core samples across the breadth of the Project. Values applied to the estimates varied between 2.2t/m<sup>3</sup> to 2.7t/m<sup>3</sup> and were assigned based on geology, weathering and mineralisation.

### **Mineral Resource Classification**

The Mineral Resource Estimate was classified in accordance with the Australasian Code for the Reporting of Exploration Results, Mineral Resources and Ore Reserves (JORC, 2012).

Mineral Resource classification was considered on the basis of drill hole spacing, continuity of mineralisation and data quality. Accurate drill hole collar and topographic surveys have been obtained for the deposits, so the spatial location of data and topography has a high level of confidence. The quality of the drilling and assaying has been confirmed through independent verification of procedures and through a satisfactory QAQC protocol.

The Grandão main (upper) pegmatite defined by 20m to 40m spaced drill holes and showing excellent continuity of pegmatite and lithium distribution has been classified as Measured Mineral Resource. The Indicated Mineral Resource was defined within areas of close spaced drilling of less than 50m by 40m, and where the continuity and predictability of the lode positions was good. The lower portion of the deposit remains undrilled. The pegmatite interpretations have been extended up to 300m past drill hole intersections. The portion which has been extrapolated up to 120m past drill holes has been classified as Inferred Mineral Resource. The deeper portion remains unclassified.

For Reservatório, the Indicated Mineral Resource was defined within areas of close spaced drilling of less than 40m by 40m, and where the continuity and predictability of the lode positions was good. The lower portion of the deposit remains undrilled. The pegmatite interpretations have been extended up to 300m past drill hole intersections. The portion which has been extrapolated up to 120m past drill holes has been classified as Inferred Mineral Resource. The deeper portion remains unclassified.

For Pinheiro, the Indicated Mineral Resource was defined within fresh material, in areas of close spaced drilling of less than 40m by 40m, and where the continuity and predictability of the lode positions was good. The lower portion of the deposit remains undrilled. The pegmatite interpretations have been extended up to 200m past drill hole intersections. The portion which has been extrapolated up to 80m past drill holes has been classified as Inferred Mineral Resource. The deeper portion remains unclassified.

The portion of the NOA pegmatite defined by 20m to 40m spaced drill holes and showing good continuity of pegmatite and Li<sub>2</sub>O distribution has been classified as Indicated Mineral Resource. The Indicated portion was extended for the full length of the pegmatite which had been exposed and mapped in the pit and was extrapolated up to 20m past drill hole intersections. Inferred Mineral Resource was assigned to those areas of the NOA deposit defined by a drill hole spacing of greater than 40m.

### **Cut-off Grades**

The shallow nature of the Project's pegmatites suggests good potential for open pit mining if sufficient resources can be delineated to consider a mining operation. The Statement of Mineral Resources have been constrained by the mineralisation solids, reported above a cut-off grade of 0.5% Li<sub>2</sub>O. Previous Whittle optimisations demonstrate reasonable prospects for eventual economic extraction utilising open pit mining methods.

### **Metallurgy**

Metallurgical test work has been conducted on the Project's pegmatites, including composite samples derived from the Grandão, Reservatório, Pinheiro, NOA and Aldeia weathered and fresh material types. Sedgman MinSol Pty Ltd ("MinSol") assisted with determining an efficient and environmentally conscious

process flowsheet for the production of a high quality spodumene concentrate grading >5.5% Li<sub>2</sub>O, whilst achieving the following key environmental and social criteria:

- Use of REACH (European Chemical Regulation) registered chemicals;
- Use of chemicals classified with low environmental toxicity;
- No use of strong acids or bases and operating at near neutral pH; and
- Dry stacked tails to minimise ground water disturbance.

The work indicated that the Project's material can contribute to the Project's plant feed to produce a minimum 5.5% Li<sub>2</sub>O concentrate at approximately 73% recovery.

### Modifying Factors

No modifying factors were applied to the reported Mineral Resource Estimate. Parameters reflecting mining dilution, ore loss and metallurgical recoveries will be considered during any future mining evaluation of the Project.

These Mineral Resources will be utilised in the Project's Definitive Feasibility Study to estimate Ore Reserves.

### Exploration Targets

In addition to the Mineral Resource estimates, Ashmore completed Exploration Targets for the Project.

The potential quantity and grade of the Project's Lithium Exploration Target is conceptual in nature. There has been insufficient exploration to estimate a Mineral Resource. It is uncertain if further exploration will result in the estimation of a Mineral Resource. The Exploration Target has been prepared and reported in accordance with the 2012 edition of the JORC Code.

The Exploration Target is based on the results of exploration activities undertaken to date and references an extensive dataset of drilling, geological mapping and surface sampling information. The drilling and surface sampling data forms the basis for grade ranges; and tonnage factors were based on wireframes generated from drilling data, as well as mapped pegmatites, surface sampling grade within mapped pegmatites and historically mined areas. Savannah plans on conducting further drilling and sampling at the Project after the completion of the ongoing DFS.

The Exploration Target by Ashmore for the Project is tabulated in **Table 7** and the regional portion of the Exploration Target subdivided by prospect is shown in **Table 8**.

**Table 7.** Exploration Target<sup>13</sup> Summary

Deposit	Tonnage Range (Mt)		Li <sub>2</sub> O %
	Lower	Upper	
<b>Reservatório</b>	5.0	7.0	0.9-1.2%
<b>Grandão</b>	4.0	8.0	1.0-1.2%

### Next Steps

Following the successful upgrade and expansion of the Project's resource, subsequent relevant work streams are expected to include:

- Additional resource drilling primarily focused on extension of the Pinheiro deposits
- Resource optimisations and pit designs which will form the basis of the DFS
- Further mapping, rock chipping and drilling to further refine exploration targets and potential conversion into resources.

### Background on the JORC Code

The Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves ('the JORC Code') is a professional code of practice that sets minimum standards for Public Reporting of minerals Exploration Results, Mineral Resources and Ore Reserves.

The JORC Code provides a mandatory system for the classification of minerals Exploration Results, Mineral Resources and Ore Reserves according to the levels of confidence in geological knowledge and technical and economic considerations in Public Reports.

Public Reports prepared in accordance with the JORC Code are reports prepared for the purpose of informing investors or potential investors and their advisors.

The JORC Code was first published in 1989, with the most recent revision being published late in 2012.

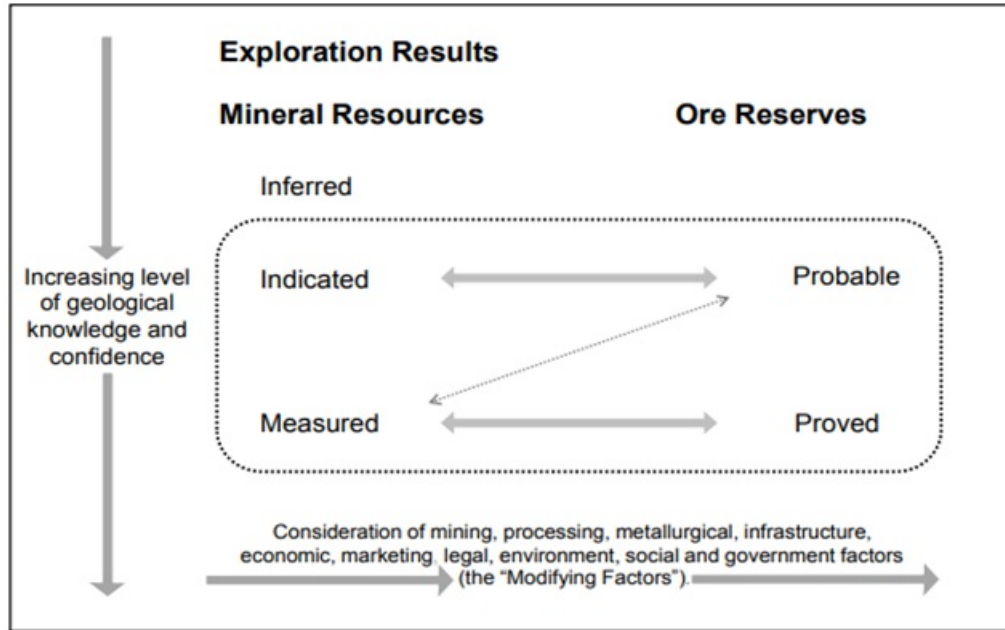

<sup>15</sup> *Cautionary Statement: The potential quantity and grade of the Exploration Targets is conceptual in nature, there has been insufficient exploration work to estimate a mineral resource and it is uncertain if further exploration will result in defining a mineral resource.*

Category	Definition
Exploration Target	A statement or estimate of the exploration potential of a mineral deposit in a defined geological setting where the statement or estimate, quoted as a range of tonnes and a range of grade (or quality), relates to mineralisation for which there has been insufficient exploration to estimate a Mineral Resource.
Mineral Resource	A concentration or occurrence of solid material of economic interest in or on the Earth's crust in such form, grade (or quality), and quantity that there are reasonable prospects for eventual economic extraction. The location, quantity, grade (or quality), continuity and other geological characteristics of a Mineral Resource are known, estimated or interpreted from specific geological evidence and knowledge, including sampling. Mineral Resources are sub-divided, in order of increasing geological confidence, into Inferred, Indicated and Measured categories.
Inferred Mineral Resource	That part of a Mineral Resource for which quantity and grade (or quality) are estimated on the basis of limited geological evidence and sampling. Geological evidence is sufficient to imply but not verify geological and grade (or quality) continuity. It is based on exploration, sampling and testing information gathered through appropriate techniques from locations such as outcrops, trenches, pits, workings and drill holes. An Inferred Mineral Resource must not be converted to an Ore Reserve. It is reasonably expected that the majority of Inferred Mineral Resources could be upgraded to Indicated Mineral Resources with continued exploration.
Indicated Mineral Resource	That part of a Mineral Resource for which quantity, grade (or quality), densities, shape and physical characteristics are estimated with sufficient confidence to allow the application of Modifying Factors in sufficient detail to support mine planning and evaluation of the economic viability of the deposit. Geological evidence is derived from adequately detailed and reliable exploration, sampling and testing gathered through appropriate techniques from locations such as outcrops, trenches, pits, workings and drill holes, and is sufficient to assume geological and grade (or quality) continuity between points of observation where data and samples are gathered. An Indicated Mineral Resource has a lower level of confidence than that applying to a Measured Mineral Resource and may only be converted to a Probable Ore Reserve.
Measured Mineral Resource	that part of a Mineral Resource for which quantity, grade (or quality), densities, shape, and physical characteristics are estimated with confidence sufficient to allow the application of Modifying Factors to support detailed mine planning and final evaluation of the economic viability of the deposit. Geological evidence is derived from detailed and reliable exploration, sampling and testing gathered through appropriate techniques from locations such as outcrops, trenches, pits, workings and drill holes, and is sufficient to confirm geological and grade (or quality) continuity between points of observation where data and samples are gathered. A Measured Mineral Resource has a higher level of confidence than that applying to either an Indicated Mineral Resource or an Inferred Mineral Resource. It may be converted to a Proved Ore Reserve or under certain circumstances to a Probable Ore Reserve.
Ore Reserve	Is the economically mineable part of a Measured and/or Indicated Mineral Resource. It includes diluting materials and allowances for losses, which may occur when the material is mined or extracted and is defined by studies at Pre-Feasibility or Feasibility level as appropriate that include application of Modifying Factors. Such studies demonstrate that, at the time of reporting, extraction could reasonably be justified. The reference point at which Reserves are defined, usually the point where the ore is delivered to the processing plant, must be stated. It is important that, in all situations where the reference point is different, such as for a saleable product, a

clarifying statement is included to ensure that the reader is fully informed as to what is being reported.

### Competent Person and Regulatory Information

The information in this announcement that relates to exploration results is based upon information compiled by Mr Dale Ferguson, Technical Director of Savannah Resources Limited. Mr Ferguson is a Member of the Australasian Institute of Mining and Metallurgy (AusIMM) and has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the December 2012 edition of the "Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves" (JORC Code). Mr Ferguson consents to the inclusion in the report of the matters based upon the information in the form and context in which it appears.

The information in this release that relates to Mineral Resources and Exploration Targets for the Grandão, Reservatório, Pinheiro and NOA deposits, as well as the Barroso Lithium Project Exploration Target is based on information compiled by Mr Shaun Searle who is a Member of the Australasian Institute of Geoscientists. Mr Searle is an employee of Ashmore Advisory Pty Ltd and independent consultant to Savannah Resources Plc. Mr Searle has sufficient experience, which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which he has undertaken to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for the Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Searle consents to the inclusion in this report of the matters based on this information in the form and context in which it appears.

The Information in this report that relates to Mineral Resources and Exploration Targets for the Aldeia deposit is based on information compiled by Mr Paul Payne, a Competent Person who is a Fellow of the Australasian Institute of Mining and Metallurgy. Mr Payne is a full-time employee of Payne Geological Services. Mr Payne has sufficient experience that is relevant to the style of mineralisation and type of deposit under consideration and to the activity being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the "Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves". Mr Payne consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

### Regulatory Information

This Announcement contains inside information for the purposes of the UK version of the market abuse regulation (EU No. 596/2014) as it forms part of United Kingdom domestic law by virtue of the European Union (Withdrawal) Act 2018 ("UK MAR").

**About Savannah**

Savannah Resources is a mineral resource development company and the sole owner of the Barroso Lithium Project (the 'Project') in northern Portugal. The Project is the largest battery grade spodumene lithium resource outlined to date in Europe and was classified as a 'Strategic Project' by the European Commission under the Critical Raw Materials Act in March 2025.

Through the Project, Savannah will help Portugal to play an important role in providing a long-term, locally sourced, lithium raw material supply for Europe's lithium battery value chain. Once in operation the Project will produce enough lithium (contained in c.190,000tpa of spodumene concentrate) for approximately half a million vehicle battery packs per year and hence make a significant contribution towards the European Commission's Critical Raw Material Act goal of a minimum 10% of European endogenous lithium production from 2030.

Savannah is focused on the responsible development and operation of the Barroso Lithium Project so that its impact on the environment is minimised and the socio-economic benefits that it can bring to all its stakeholders are maximised.

The Company is listed and regulated on the London Stock Exchange's Alternative Investment Market (AIM) and trades under the ticker "SAV".

<b>Geological interpretation</b>	<ul style="list-style-type: none"> <li>Confidence in (or conversely, the uncertainty of) the geological interpretation of the mineral deposit.</li> <li>Nature of the data used and of any assumptions made.</li> <li>The effect, if any, of alternative interpretations on Mineral Resource estimation.</li> <li>The use of geology in guiding and controlling Mineral Resource estimation.</li> <li>The factors affecting continuity both of grade and geology.</li> </ul>	<ul style="list-style-type: none"> <li>The confidence in the geological interpretation is based on visual confirmation of the mineralisation.</li> <li>Geochemistry and geology are used to confirm the mineralisation.</li> <li>The MBLP comprises a series of granitic rocks of the region's strongly deformed metasediments. The dykes and sills range from 10m to 100m in true width. The mineralisation is hosted in a to 10m in true width. The approximately 420m and recent small-scale mining activity / shallow pits to provide feed for the plant.</li> <li>Infill drilling has supported the interpretation is considered reasonable.</li> <li>Observations from the outcrop and infill drilling, confirm the geological interpretation.</li> <li>Infill drilling has confirmed the grade of the mineralisation.</li> </ul>
<b>Dimensions</b>	<ul style="list-style-type: none"> <li>The extent and variability of the Mineral Resource expressed as length (along strike or otherwise), plan width, and depth below surface to the upper and lower limits of the Mineral Resource.</li> </ul>	<ul style="list-style-type: none"> <li>The NOA Mineral Resource is based on the length of 420m and includes 570mRL.</li> </ul>

Estimation and modelling techniques	JORC Code explanation	Comments
	<p>appropriateness of the estimation technique(s) applied and key assumptions, including treatment of extreme grade values, domaining, interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</p> <ul style="list-style-type: none"> <li>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</li> <li>The assumptions made regarding recovery of by-products.</li> <li>Estimation of deleterious elements or other non-grade variables of economic significance (eg sulphur for acid mine drainage characterisation).</li> <li>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</li> <li>Any assumptions behind modelling of selective mining units.</li> <li>Any assumptions about correlation between variables.</li> <li>Description of how the geological interpretation was used to control the resource estimates.</li> <li>Discussion of basis for using or not using grade cutting or capping.</li> <li>The process of validation, the checking process used, the comparison of model data to drill hole data, and use of reconciliation data if available.</li> </ul>	<p>parameters derived (OK) was used to estimate Surpac software. Linear grade Mineral Resource due to the grade of Fe<sub>2</sub>O<sub>3</sub> was estimated to eliminate Fe introduced in the grade of Fe<sub>2</sub>O<sub>3</sub> was determined to Li<sub>2</sub>O (%), Ta (ppm), Fe (%), were interpolated into the block model using the respective oxide values.</p> <ul style="list-style-type: none"> <li>A Surpac block model was created for mineralisation, with block dimensions of 1.25m by 2.5m by 2.5m. A block size of 1.25m by 2.5m by 2.5m was selected on the results of an orientated 'ellipsoid' search to account for the variations in grade. The variations in grade were taken from the variogram and used for each domain. A minimum of 6 samples. For 80m, with a minimum of 4 samples was used for each domain. No assumptions were made.</li> <li>Correlation analysis was conducted. Li<sub>2</sub>O has little correlation with Fe.</li> <li>The mineralisation was controlled by internal lithium bearing minerals. A nominal 0.4% Li<sub>2</sub>O cut-off grade was used.</li> <li>The wireframes were used to create the domains. Following a review of the probability plots and noting the determined that the application of the cut-off grade was appropriate.</li> <li>Validation of the model and composite grades and block model grades showed good correlation.</li> </ul>
Moisture	<ul style="list-style-type: none"> <li>Whether the tonnages are estimated on a dry basis or with natural moisture, and the method of determination of the moisture content.</li> </ul>	<ul style="list-style-type: none"> <li>Tonnages and grades were reported on a dry basis.</li> </ul>
Cut-off parameters	<ul style="list-style-type: none"> <li>The basis of the adopted cut-off grade(s) or quality parameters applied.</li> </ul>	<ul style="list-style-type: none"> <li>The Statement of Mineral Resource, report on the mineralisation solids, report on the Whittle optimisations demonstrating economic extraction utilising work indicated that the material has an approximately 75% recovery.</li> <li>This Mineral Resource was estimated on an Ore Reserve basis.</li> </ul>
Mining factors or assumptions	<ul style="list-style-type: none"> <li>Assumptions made regarding possible mining methods, minimum mining dimensions and internal (or, if applicable, external) mining dilution. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential mining methods, but the assumptions made regarding mining methods and parameters when estimating Mineral Resources may not always be rigorous. Where this is the case, this should be reported with an explanation of the basis of the mining assumptions made.</li> </ul>	<ul style="list-style-type: none"> <li>Ashmore has assumed the use of conventional mining techniques.</li> <li>A high level Whittle optimisation was used to determine the economic extraction.</li> </ul>
Metallurgical factors or assumptions	<ul style="list-style-type: none"> <li>The basis for assumptions or predictions regarding metallurgical amenability. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential metallurgical methods, but the assumptions regarding metallurgical treatment processes and parameters made when reporting Mineral Resources may not always be rigorous. Where this is the case, this should be reported with an explanation of the basis of the metallurgical assumptions made.</li> </ul>	<ul style="list-style-type: none"> <li>Metallurgical test work was conducted on composite samples derived from the MBLP core processing plant. The test work indicated that the material is amenable to efficient and environmentally sound production of a high quality product whilst achieving the following: <ul style="list-style-type: none"> <li>a. Use of REACH chemicals;</li> <li>b. Use of chemicals that are not listed on the REACH list;</li> <li>c. No use of strong acids or alkalis;</li> <li>d. Dry stacked tails to land.</li> </ul> </li> <li>The work indicated that the material can be used to produce a 5.5% Li<sub>2</sub>O product.</li> </ul>
Environmental factors or assumptions	<ul style="list-style-type: none"> <li>Assumptions made regarding possible waste and process residue disposal options. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and processing operation. While at this stage the determination of potential environmental impacts, particularly for a greenfields project, may not always be well advanced, the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</li> </ul>	<ul style="list-style-type: none"> <li>No assumptions have been made. Savannah will work to mitigate future mining or mineral processing impacts.</li> </ul>
Bulk density	<ul style="list-style-type: none"> <li>Whether assumed or determined. If assumed, the basis for the assumptions. If determined, the method used, whether wet or dry, the frequency of the measurements, the nature, size and representativeness of the samples.</li> <li>The bulk density for bulk material must have been measured by methods that adequately account for void spaces (vugs, porosity, etc), moisture and differences between rock and alteration zones within the deposit.</li> <li>Discuss assumptions for bulk density estimates used in the evaluation process of the different materials.</li> </ul>	<ul style="list-style-type: none"> <li>Bulk density measurements were obtained from diamond core drilled at the MBLP core processing plant. The weathered sample was used to determine the porosity of the weathered sample. A total of 306 measurements were obtained from weathered and unweathered samples.</li> <li>Bulk densities ranging between 2.5 and 3.0 g/cm<sup>3</sup> were obtained from block model dependent on lithium content.</li> </ul>
Classification	<ul style="list-style-type: none"> <li>The basis for the classification of the Mineral Resources into varying confidence categories.</li> <li>Whether appropriate account has been taken of all relevant factors (i.e. relative confidence in tonnage/grade estimations, reliability of input data, confidence in continuity of geology and metal values, quality, quantity and distribution of the data).</li> <li>Whether the result appropriately reflects the Competent Person's view of the</li> </ul>	<ul style="list-style-type: none"> <li>The Mineral Resource estimate was prepared in accordance with the 2012 Edition of the 'Australian Mineral Resources and Reserves (Reporting Guidelines)' (JORC). The NO and Inferred Mineral Resources were based on the continuity of the indicated close spaced drilling of less than 10m. The indicated close spaced drilling of less than 10m was assigned to areas where drill holes were intercepted by few drill holes. The input data is comprehensive.</li> </ul>

Criteria	JORC Code explanation	Commentary
		<p>The input data is comprehensive and the model is not biased in favour or misrepresents mineralised zones. The model is based on a robust geological interpretation of the data and is confirmed by infill drilling within the block model shows good grades.</p> <p>The Mineral Resource estimate is based on the Competent Person's view of the deposit.</p>
<b>Audits or reviews</b>	<ul style="list-style-type: none"> <li>The results of any audits or reviews of Mineral Resource estimates.</li> </ul>	<ul style="list-style-type: none"> <li>Internal audits have been conducted on technical inputs, methodology and the applied level of Indicated and Measured grades. The drill holes are of good quality and the drill holes are recognised by a recognised laboratory.</li> </ul>
<b>Discussion of relative accuracy/ confidence</b>	<ul style="list-style-type: none"> <li>Where appropriate a statement of the relative accuracy and confidence level in the Mineral Resource estimate using an approach or procedure deemed appropriate by the Competent Person. For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors that could affect the relative accuracy and confidence of the estimate.</li> <li>The statement should specify whether it relates to global or local estimates, and, if local, state the relevant tonnages, which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used.</li> <li>These statements of relative accuracy and confidence of the estimate should be compared with production data, where available.</li> </ul>	<ul style="list-style-type: none"> <li>The geometry and continuity of the mineralised zones is good, and the drill holes are of good quality and the drill holes are recognised by a recognised laboratory.</li> <li>The Mineral Resource estimate is based on the Competent Person's view of the deposit.</li> <li>A total of 22,000t at 1.2% Cu is based on historical production figures.</li> </ul>
